Workshop: Console Tic-Tac-Toe

In this workshop, we will create a simple two-player tic-tac-toe game. Here is how the game is going to look in the end:

```
Player one name: peter
Player two name: george
peter would you like to play with 'X' or 'O'? X
This is the numeration of the board:
              3
        8
              9
          peter starts first!
peter choose a free position [1-9]: 1
george choose a free position [1-9]: 5
           peter choose a free position [1-9]:
peter choose a free position [1-9]: 2
   Χ
          X
          0
qeorge choose a free position [1-9]: 4
   X
          X
   O
          O
peter choose a free position [1-9]: 3
                 X
   X
          X
   0
          0
peter won!
Process finished with exit code 0
```

The Main Logic

Global Variables

The global variables will be player one, player two, board (the state of the game), and loop (boolean to check if the game should continue or not)

Implementation

Let us now create our main logic of the game

```
player one = None
player two = None
board = [[" ", " ", " "], [" ", " ", " "], [" ", " "]]
setup()
current = player one
other = player two
loop = True
while loop:
    play(current, board)
    current, other = other, current
```

- We create our global variables player_one, player_two (None to start with), board (empty to start with), and **loop** (game loop)
- We also create variables current and other (to switch turns of the players)
- We call a setup() function, which we will implement later (it should take the info of the players and draw the initial state of the board)
- We create a while loop to keep playing until a player wins
- In there, we call a function called **play()** which will take the **choice** of the current player and **apply** his/her choice on the board
- Finally, we switch the players, so in the next iteration, the other player should choose

Creating the Setup() Function

```
def setup():
   global player one, player two
   player one name = input("Player one name: ")
   player two name = input("Player two name: ")
   player_one_sign = input(f"{player_one_name} would you like to play with 'X' or 'O'? ")
   player two sign = 'X' if player one sign == '0' else '0'
   player one = [player one name, player one sign]
   player two = [player two name, player two sign]
   print("This is the numeration of the board:")
   print("| 1 | 2 | 3 |")
   print("| 4 | 5 | 6 |")
                      | 9 |")
   print("| 7 |
                   8
   print(f"{player one name} starts first!")
```

- We take the **names** of the two players
- Then we ask player one for his sign and set the sign of the second player
- We save the info in the global variables player_one and player_two as a list of their names and signs
- We display some **info** about the game **rules** and start with player one

Creating the Play() Function

Now, let us implement the play() function, which will ask the current player to choose the following action and apply his/her sign on the board

```
def play(current, board):
    choice = int(input(f"{current[0]} choose a free position [1-9]: "))
    row = ceil(choice / 3) - 1
    col = choice % 3 - 1
    board[row][col] = current[1]
    draw board (board)
    check if won(current, board)
```

- Here we ask the player to choose a **free space** to apply his/her sign
- We create the variables **row** and **col**, which calculate the **row** and **col** of the selected **label** (don't forget to **import ceil** from the math library)
- Then we apply the sign of the current player on the board
- We call **two functions** which we will implement next:
 - o draw board(board) loops through the board and draws its current state
 - o check_if_won(current, board) checks if the current player has won after choosing his action

Creating the Draw_board() Function

```
def draw board(board):
    for row in board:
       print('| ', end="")
       print(' | '.join([str(x) for x in row]), end="")
       print(' |')
```

Here we **loop** through each **row** in the board and print its **state**

Creating the Check if won() Function

```
def check if won(current, board):
    global loop
    first row = all([x == current[1]  for x  in board[0]])
    second row = all([x == current[1] for x in board[1]])
    third row = all([x == current[1] for x in board[2]])
    first column = all(x == current[1] for x in [board[0][0], board[1][0], board[2][0]])
    second column = all(x == current[1]  for x  in [board[0][1], board[1][1], board[2][1]])
    third column = all(x == current[1]  for x  in [board[0][2], board[1][2], board[2][2]])
    first diagonal = all(x == current[1] for x in [board[0][0], board[1][1], board[2][2]])
    second diagonal = all(x == current[1]  for x  in [board[2][0], board[1][1], board[0][2]])
    if any([first row, second row, third row, first column, second column,
            third column, first diagonal, second diagonal]):
        print(f"{current[0]} won!")
        loop = False
```

- In this function, we first use the **global loop** variable, because we will use it later
- Then we create a **boolean** variable for each **win condition**
- We then check if any of these conditions is **True** and if there are, we print that the **current player has won** and then **stop the loop** (we set the loop variable to **False**)

1. BONUS

- Try writing validation logic for:
 - The signs can only be "X" and "O"
 - The users can only choose from the numbers 1 to 9
 - The users can only choose a free space
- Try adding error messages for those validations
